During drilling of an oil or gas well, a quantity of a drilling fluid is pumped into the drill string, through the drill pipe and out a drill bit through nozzles in the drill bit. The drill bit rotates, cutting into a rock formation. The cuttings are carried upward by the drilling fluid to the surface. As the cuttings reach the surface, it is desirable to separate the drilling fluid and the cuttings to avoid contamination of fresh water supplies. This is achieved by bringing the cuttings to the surface through an annular space between the walls of the drill pipe and the walls of the well bore. As the drill bit rotates, drilling fluid is circulated through the drill pipe, exits through the nozzles in the drill bit and returns to the surface through the annular space. A filter or shale shaker is used to remove solids from the drilling fluid before returning the drilling fluid to the surface. A commonly used drilling fluid is a drilling mud, which is a suspension of solid particles in a liquid vehicle. The solid particles are typically selected to be the least reactive with the formation. Such solid particles may include, but are not limited to, shale, sand, diatomaceous earth, or mica. Shale shakers generally fall into two categories—fixed and mobile. Fixed shale shakers are designed to suspend solids removed from a well bore in a stable manner until the solids can be separated from the drilling fluid and conveyed to another location for further processing. Fixed shale shakers typically include a perforated basket, or other screen, and one or more filter bags that filter drilling fluid. The filter
