Radial or tangential expansion Radial (or tangential) expansion is the expansion of an optical surface or mirror (including curved optics) due to its bending of rays of light. Diagram of tangential expansion Because the expansion is along the path of a ray of light, it is often referred to as "radial" (n=1 in the diagram). We will use both "radial" and "tangential" where appropriate throughout this document. There are no rigorous equations for estimating the effect of radial expansion. Common sense and experience can serve as guides for estimating the magnitude of this aberration. The effect of tangential expansion is proportional to the magnification of the object being viewed, and that magnification is derived from the ratio of the object distance and focal length. For example, an object 1/2 unit away from the image plane (focal plane) viewed through a lens having an effective focal length of 1mm will project 1mm of focal length onto the image plane. It is not the easiest error to estimate. The following calculation may be helpful. Take a picture of your hand and thumb held horizontally at a distance of 2 inches (51mm) with a 7mm lens. Then take that picture from 3 inches (75mm) away. The two images will appear the same at first, but if you look carefully you will find that the 7mm image appears to be slightly enlarged (
